PREFACE

This booklet was prepared under the direction of the Committee on Research of the American Institute of Steel Construction, Inc. as part of a series of publications on special topics related to fabricated structural steel. Its purpose is to serve as a supplemental reference to the AISC Manual of Steel Construction to assist practicing engineers engaged in building design.

The design guidelines suggested by the authors that are outside the scope of the AISC Specifications or Code do not represent an official position of the Institute and are not intended to exclude other design methods and procedures. It is recognized that the design of structures is within the scope of expertise of a competent licensed structural engineer, architect, or other licensed professional for the application of principles to a particular structure.

The sponsorship of this publication by the American Iron and Steel Institute is gratefully acknowledged.

The information presented in this publication has been prepared in accordance with recognized engineering principles and is for general information only. While it is believed to be accurate, this information should not be used or relied upon for any specific application without competent professional examination and verification of its accuracy, suitability, and applicability by a licensed professional engineer, designer, or architect. The publication of the material contained herein is not intended as a representation or warranty on the part of the American Institute of Steel Construction, Inc. or the American Iron and Steel Institute, or of any other person named herein, that this information is suitable for any general or particular use or of freedom infringement of any patent or patents. Anyone making use of this information assumes all liability arising from such use.
LOAD AND RESISTANCE FACTOR DESIGN OF W-SHAPES ENCASED IN CONCRETE

INTRODUCTION

Structural members comprised of steel shapes in combination with plain or reinforced concrete have been utilized by engineers for many years. Early structures simply took advantage of the protection that the concrete afforded to the steel shapes for resistance to fire and corrosion. But research on the strength of such members was conducted in the early 1900s, and design provisions were formulated by 1924. More recently, with the advent of modern composite frame construction in high rise buildings, engineers developed new rational methods to take advantage of the stiffening and strengthening effects of concrete and reinforcing bars on the capacity of encased steel shapes.

This Guide presents design tables for composite columns, developed under the sponsorship of the American Institute of Steel Construction (AISC) as an aid to the practicing structural engineer in the application of the AISC Load and Resistance Factor Design (LRFD) Specification for Structural Steel Buildings. The information presented supplements that found in the AISC LRFD Manual. Background on the LRFD criteria for composite columns may be found in References 5 and 6. Engineers interested in Allowable Stress Design (ASD) are encouraged to consider the procedure developed previously by the Structural Stability Research Council (SSRC). The SSRC procedure is not presently included in the AISC ASD Specification.

The reader is cautioned that independent professional judgment must be exercised when data or recommendations set forth in this Guide are applied. The publication of the material contained herein is not intended as a representation or warranty on the part of the American Institute of Steel Construction, Inc.—or any person named herein—that this information is suitable for general or particular use, or freedom from infringement of any patent or patents. Anyone making use of this information assumes all liability rising from such use. The design of structures should only be performed by or under the direction of a competent licensed structural engineer, architect, or other licensed professional.

SCOPE

This Guide is specifically for composite columns comprised of rolled wide flange shapes encased in reinforced structural concrete with vertical deformed reinforcing bars and lateral ties. Composite columns are defined in Section II of the LRFD Specification as a "steel column fabricated from rolled or built-up steel shapes and encased in reinforced structural concrete or fabricated from steel pipe or tubing and filled with structural concrete." Further, the Specification requires in Section I2.1 that the cross sectional area of the steel shape comprise at least four percent of the total composite cross section. The Commentary to the Specification states that when the steel shape area is less, the column should be designed under the rules for conventional reinforced concrete columns.

Part 1 of this Guide includes a discussion of composite frame construction, practical uses of composite columns, their advantages and limitations, and a review of important practical design considerations. A summary of the pertinent LRFD rules is presented and compared to other methods. A set of suggested design details is given in Part 2, showing placement of reinforcing bars and ties, as well as treatment of joints and base plates. Five design examples are given in Part 3 to illustrate how the tables were derived and how they are applied. Finally, a comprehensive set of tables is presented in Part 4 to assist the designer in the rapid selection of the most economical section to resist required values of factored load and moment.

PART 1: USE AND DESIGN OF COMPOSITE COLUMNS

Composite Frame Construction

Although engineers since the 1930s have encased structural steel shapes in concrete for fireproofing and corrosion protection, it was not until the development and popularity of modern composite frame construction in the 1960s that composite columns again became a common and viable structural member type. The late Dr. Fazlur Khan, in his early discussions of structural systems for tall buildings, first proposed the concept of a composite frame system utilizing composite columns as part of the overall wind and earthquake resisting frame. Since that time composite frame construction has been adopted for many high rise buildings all over the world. Its usage, with the composite column as the key element, is well documented in the work of the Council on Tall Buildings and numerous other publications.

The term "composite frame structure" describes a building employing concrete encased steel columns and a composite floor system (structural steel and concrete filled steel deck).
The bare steel columns resist the initial gravity, construction, and lateral loads until such time as the concrete is cast around them to form composite columns capable of resisting the total gravity and lateral loads of the completed structure. In a composite frame building, the structural steel and reinforced concrete combine to produce a structure having the advantages of each material. Composite frames have the advantage of speed of construction by allowing a vertical spread of the construction activity so that numerous trades can engage simultaneously in the construction of the building. Inherent stiffness is obtained with the reinforced concrete to more easily control the building drift under lateral loads and reduce perception to motion. The light weight and strength obtained with structural steel equates to savings in foundation costs.

Traditionally in steel framed buildings or reinforced concrete buildings, stability and resistance to lateral loads are automatically provided as the structure is built. Welded or bolted moment connections are made or braces are connected between columns in a steel building immediately behind the erection of the steel frame to provide stability and resistance to lateral loads. Shear walls, or the monolithic casting of beams and columns, provide stability and resistance to lateral loads soon after the concrete has cured for reinforced concrete buildings. However, for composite frame structures, the final stability and resistance to design lateral loads is not achieved typically until concrete around the erection steel frame has cured, which typically occurs anywhere from a minimum of six to as much as 18 floors behind the erection of the bare steel frame. This sequence of construction is shown schematically in Fig. 1. Thus, as discussed subsequently, temporary lateral bracing of the uncured portion of the frame will typically be required.

Practical Uses of Composite Columns

Practical applications for the use of composite columns can be found in both low rise and high rise structures. In low rise structures such as a covered playground area, a warehouse, a transit terminal building, a canopy, or porte cochere, it may be necessary or desirable to encase a steel column with concrete for aesthetic or practical reasons. For example, architectural appearance, resistance to corrosion, or protection against vehicular impact may be important. In such structures, it may be structurally advantageous to take advantage of the concrete encasement of the rolled steel shape that supports the steel roof structure by designing the member as a composite column resisting both gravity and lateral loads.

In high rise structures, composite columns are frequently used in the perimeter of "tube" buildings where the closely spaced columns work in conjunction with the spandrel beams (either steel or concrete) to resist the lateral loads. In some recent high rise buildings, giant composite columns placed at or near the corners of the building have been utilized as part of the lateral frame to maximize the resisting moment provided by the building's dead load. Composite shear walls with encased steel columns to carry the floor loads have also been utilized in the central core of high rise buildings. Frequently, in high rise structures where floor space is a valuable and income producing commodity, the large area taken up by a concrete column can be reduced by the use of a heavy encased rolled shape to help resist the extreme loads encountered in tall building design. Sometimes, particularly at the bottom floors of a high rise structure where large open lobbies or atriums are planned, a heavy encased rolled shape as part of a composite column is a necessity because of the large load and unbraced length. A heavy rolled shape in a composite column is often utilized where the column size is restricted architecturally and where reinforcing steel percentages would otherwise exceed the maximum code allowed values.

Advantages, Disadvantages, and Limitations

Some of the advantages of composite columns are as follows:

1. Smaller cross section than required for a conventional reinforced concrete column.
2. Larger load carrying capacity.
3. Ductility and toughness available for use in earthquake zones.
4. Speed of construction when used as part of a composite frame.
5. Fire resistance when compared to plain steel columns.
6. Higher rigidity when part of a lateral load carrying system.
7. Higher damping characteristics for motion perception in tall buildings when part of a lateral load carrying system.
8. Stiffening effect for resistance against buckling of the rolled shape.

There are also, of course, some disadvantages and limitations. In high rise composite frame construction, design engineers sometimes have difficulty in controlling the rate and magnitude of column shortening of the composite column with respect to adjacent steel columns or shear walls. These problems are exacerbated by the wide variation in construction staging often experienced in the zone between the point where the steel erection columns are first erected and the point where concrete is placed around the steel to form the composite column. This variation in the number of floors between construction activities has made it difficult to calculate with accuracy the effect of column shortening. Creep effects on the composite columns with respect to the all-steel core columns, or between shear walls, can also be troublesome to predict for the designer. The net effect of these problems can be floors that are not level from one point to another. One solution to these problems has been the measurement of column splice elevations during the course of construction, with subsequent corrections in elevation using steel shims to compensate for differences between the calculated and measured elevation.

As with any column of concrete and reinforcing steel, the designer must be keenly aware of the potential problems in reinforcing steel placement and congestion as it affects the constructability of the column. This is particularly true at beam-column joints where potential interference between a steel spandrel beam, a perpendicular floor beam, vertical bars, joint ties, and shear connectors can all cause difficulty in reinforcing bar placement and lead to honeycombing of the concrete. Careful attention must be given to the detailing of composite columns by the designer. Analytical and experimental research is needed in several aspects of composite column design. One area requiring study is the need, or lack thereof, of a mechanical bond between the steel shape and the surrounding concrete. Several papers\textsuperscript{16, 17} have discussed this question, but additional work is required to quantify the need for shear connectors with a practical design model for routine design office use. There presently is a question about transfer of shear and moment through a beam-column joint. This concern is of particular importance for seismic regions where large cyclical strain reversals can cause a serious degradation of the joint. Initial research has been completed at the University of Texas at Austin\textsuperscript{24} and is ongoing at Cornell University on physical test models to study various joint details in composite columns.

Practical Design Considerations

Fire Resistance

Composite columns, like reinforced concrete columns, have an inherent resistance to the elevated temperatures produced in a fire by virtue of the normal concrete cover to the reinforcing steel and structural steel. It is standard practice to provide a minimum of one and one-half inch of concrete cover to the reinforcing steel of a composite column (concrete cover is specified in ACI 318-89 Section 7.7.1).\textsuperscript{18} Chapter 43 of the Uniform Building Code states that reinforced concrete columns utilizing Grade A concrete (concrete made with aggregates such as limestone, calcareous gravel, expanded clay, shale, or others containing 40 percent or less quartz, chert, or flint) possess a four-hour rating with one and one-half inch cover. A four-hour rating is the maximum required for building structures.

Tables of fire resistance rating for various insulating materials and constructions applied to structural elements are published in various AISI booklets\textsuperscript{19, 20, 21} and in publications of the Underwriters Laboratory, Inc.

Longitudinal Reinforcing Bar Arrangement

Composite columns can take on just about any shape for which a form can be made and stripped. They can be square, rectangular, round, triangular, or any other configuration, with just about any corresponding reinforcing bar arrangement common to concrete columns. For use in composite frame construction, however, square or rectangular columns
are the most practical shape, with bar arrangements tending to place the vertical reinforcing bars at or near the four corners of the column. Figure 2 shows preferred arrangements which allow spandrel beams and a perpendicular floor beam to frame into the encased steel shape without interrupting the continuous vertical bars. Such arrangements also generate the maximum design capacity for the column.

Although there are no explicit requirements for longitudinal bar spacing in the LRFD Specification, it is advisable to establish minimum limits so that concrete can flow readily in spaces between each bar and between bars and the encased steel shape.

Minimum spacing criteria will also prevent honeycombing and cracks caused by high bond stresses between bars. Past experience with reinforced concrete columns has shown that the requirements established by the ACI 318 Code have provided satisfactory performance. These spacing and cover requirements have been used in the formulation of this design aid and as diagramed in Fig. 3 and listed below:

1. Minimum concrete cover over vertical bars and ties shall be 1½-in. (LRFD Specification, Section I2.1.b).
2. Clear distance between longitudinal bars shall not be less than 1½ bar diameters or 1½-in. minimum (ACI 318-89 Section 7.6.3).
3. The clear distance limitations apply also to contact lap splices and adjacent bars (ACI 318-89 Section 7.6.4).
4. Clear distance between longitudinal bars and steel shape shall be 1½ bar diameters or 1½-in. minimum.

**Ties**

Reinforcing steel cages (longitudinal bars and ties) must usually be set after and around the steel column. Because the steel column is erected in an earlier erection sequence, only open U-shaped ties are suitable for composite columns. Ties are used to provide lateral stability of the longitudinal bars and confinement of the concrete. The requirements of the LRFD specification and certain requirements of the ACI 318-89 code not specifically addressed by the LRFD specification should be satisfied as follows:

1. The cross sectional area of the tie shall be at least 0.007 square inches per inch of tie spacing (LRFD Specification I2.1.b).
2. The spacing of the ties shall not be greater than two-thirds of the least dimension of the cross section (LRFD Specification I2.1.b).
3. The spacing of ties shall not be greater than 16 longitudinal bar diameters or 48 tie bar diameters (ACI 318-89 Section 7.10.5.1).
4. Ties shall be at least #4 in size for #11, #14, #18, and bundled longitudinal bars, and #3 in size for all other bars (ACI 318-89 Section 7.10.5.1).
5. Ties shall be arranged such that every corner and alternate bar shall have lateral support provided by a corner of a tie, with an inclusive angle of not more than 135° and no bar shall be further than 6 inches clear on each side along the tie from such a laterally supported bar (ACI 318-89 Section 7.10.5.3).
6. A lap splice of two pieces of an open tie shall be at least equal to 1.3 times the tensile development length for the specified yield strength (ACI 318-89 Section 12.13.5).

Suggested details for composite column ties are shown in Typical Details 1, 2, and 3 of Part 2.

**Longitudinal Reinforcing Bar Splices**

The requirements for splicing vertical longitudinal reinforcing bars for composite columns shall follow the same rules as apply for conventional reinforced concrete columns as specified in Chapter 12 of the ACI 318-89 Code. Several additional comments should be made for composite columns. First, additional vertical longitudinal restraining bars (LRFD Specification I2.1.b) should be used between the corners where the continuous load carrying bars are located in composite frame construction. These bars usually cannot be continuous because of interruption with intersecting framing members at the floor line. They are often required to satisfy the spacing requirements for vertical longitudinal bars shown as follows:
The cross section area of longitudinal reinforcement shall be at least equal to 0.007 square inches per inch of bar spacing (LRFD Specification I2.1.b).

Second, it is suggested that, in high rise composite frame construction, the vertical bar splices be located at the middle clear height of the composite column. This point is usually near the inflection point (zero moment) of the column where the more economical compression lap splices or compression butt splices may be used. The more expensive tension lap or tension butt splices may be required if splices are made at the floor line.

A suggested composite column splice detail is shown in Typical Detail 1 of Part 2.

**Connection of Steel Beam to Encased Wide Flange**

In composite frame construction, steel spandrel beams and/or perpendicular floor beams often frame into the composite column at the floor level. Sometimes these beams will be simply supported floor beams where conventional double-angle framed beam connections (LRFD Manual, Part 5) or single-plate shear connections may be utilized. More often, however, the steel spandrel beams will be part of the lateral load resisting system of the building and require a moment connection to the composite column. Practicality will often dictate that the larger spandrel beam (frequently a W36 in tall buildings) be continuous through the joint with the smaller erection column (often a small W14) interrupted and penetration welded to the flanges of the spandrel beam. To increase the speed of erection and minimize field welding, the spandrel beam and erection column are often prefabricated in the shop to form "tree columns" or "tree beams" with field connections at the mid-height of column and midspan of spandrel beam using high strength bolts. See Typical Detail 5, Part 2.

The engineer must concern himself with the transfer of forces from the floor beams to the composite column. For simply supported beams not part of the lateral frame, the simplest method to transfer the beam reaction to the composite column is through a standard double-angle or single-plate shear connection to the erection column. It is then necessary to provide a positive shear connection from the erection column to the concrete along the column length to ensure transfer of the beam reaction to the composite column cross section. The simplest method to accomplish this is by the use of standard headed shear connectors, preferably shop welded to the wide flange column. For moment connected spandrel beams, the beam shear and unbalanced moment must be transferred to the composite column cross section. Different transfer mechanisms have been tested at the University of Texas at Austin.\(^2\)

Several suggested details are shown in Details 1 and 2 of Part 2.

**Shear Connectors**

As discussed in the previous section, it is necessary to provide a positive shear connection transfer from the floor beam to the encased steel column when the beam connection is made directly to the encased steel column. It is likely that a significant portion of this reaction can be transferred in bond between the encased section and the concrete as reported in Reference 14. An estimate of this value can be made from Equation 5 of Reference 16 which is based on the results of a limited number of push tests in which a steel column is encased in a concrete column.

\[
P_d = \frac{3.6b_f(0.09f_c' - 95)l_c}{k}
\]

where

- \(P_d\) = allowable load for the encased shape, lb
- \(b_f\) = steel flange width of encased shape, in.
- \(f_c'\) = concrete compressive strength, psi
- \(l_c\) = encased length of steel shape, in.
- \(k\) = constant \(\approx 5\)

Converting to an average ultimate bond stress "\(u\)" using only the flange surfaces as being effective and applying a safety factor of five as reported in the tests.

\[
u = \frac{P_d \times 5}{4b_f l_c} = \frac{3.6 \times b_f(0.09f_c' - 95)l_c \times 5}{4b_f l_c} = 0.9(0.09 \times 5,000 - 95) = 320\, \text{psi}
\]

Consider a typical case of a W14x90 encased column in 5,000 psi concrete with a floor-to-floor height \((h_o)\) of 13 feet. The average ultimate bond stress is

\[
u = 0.9(0.09 \times 5,000 - 95) = 320\, \text{psi}
\]

The ultimate shear force that could be transferred by bond is

\[
u = u \times h_o \times 4b_f = \frac{320 \times (13 \times 12) \times (4 \times 14.5)}{1,000} = 2,895\, \text{kips}
\]

These results indicate that typical floor reactions on the composite column could be easily transferred by bond alone.

The above discussion considered the case where axial load alone is transferred from the encased steel section to the concrete. For beam-columns where high bending moments may exist on the composite column, the need for shear connectors must also be evaluated. Until such time as research data is provided, the following simplistic evaluation may be made. Assume a situation where a composite column is part of a lateral load resisting frame with a point of inflection at mid-column height and a plastic neutral axis completely outside the steel cross section (similar to Fig. 4 except for plastic neutral axis location). An analogy can be made between this case and that of a composite beam where shear connectors are provided uniformly across the member length.
between the point of zero moment and maximum moment. The ultimate axial force to be transferred between the encased steel column and the concrete over the full column height is \(2AF_y\), where \(A\) is the steel column area and \(F_y\) is its yield strength. Assuming a bond strength is available in this case similar to the case of the push test discussed above, then shear connectors would theoretically be required when \(2AF_y\) is greater than the ultimate bond force. In the previous example, assume an A36 W 14×90 erection column is used. Then,

\[
2AF_y = 2 \times 26.5 \times 36 = 1,908 \text{ kips}
\]

This is less than the available shear transfer from bond, which was calculated as 2,895 kips.

Again, it is shown that bond stress alone can transfer the shear between the encased shape and the concrete, assuming no loss in bond occurs as a result of tensile cracking at high moments.

The composite beam-column design tables presented in Part A assume a nominal flexural strength based on the plastic stress distribution of the full composite cross section. To validate this assumption, the LRFD specification commentary in Section 14, requires a transfer of shear from the steel to the concrete with shear connectors. Therefore, until further research is conducted on the loss of bond between the encased steel section and the concrete, and until more comprehensive push tests are run, the following suggestions are made with regard to shear connectors on composite columns:

1. Provide shear connectors on the outside flanges where space permits. Where space does not permit, provide shear connectors on the inside flange staggered either side of the web.
2. Provide shear connectors in sufficient quantity, spaced uniformly along the encased column length and around the column cross section between floors, to carry the greater of the following minimum shear transfer forces as applicable:
   a. The sum of all beam reactions at the floor level.
   b. Whenever the ratio of the required axial strength to the factored nominal axial strength, \(\frac{P_e}{\phi P_n}\), is less than 0.3, a force equal to \(F_e\) times the area of steel on the tensile side of the plastic neutral axis in order to sustain a moment equal to the nominal flexural strength of the composite cross section. The ratio 0.3 is used as an arbitrary value to distinguish a composite column subjected to predominantly axial load from one subjected to predominantly moment. Consideration must be given to the fact that this moment is reversible.
3. The maximum spacing of shear connectors on each flange is suggested to be 32 inches.

If minimum shear connectors are provided according to the guidelines identified herein, it is reasonable to assume compatibility of strains between concrete and encased steel to permit higher strains than 0.0018 under axial load alone. This strain level has been identified in Reference 7 and LRFD Commentary, Section 12.1, as a point where unconfined concrete remains unspalled and stable. Therefore, a slight increase in the maximum usable value of reinforcing steel stress from 55 ksi, corresponding to 0.0018 axial strain, to 60 ksi, the yield point of ASTM A615 Grade 60 reinforcing steel, would seem to be justified. Such an approach has been adopted in this Guide. The use of shear connectors also allows the full plastic moment capacity to be counted upon when \(\frac{P_e}{\phi M_n}\) is less than 0.3 (LRFD Commentary, 14) instead of the reduction specified in LRFD Specification, Section 14.

Suggested details for shear connectors on composite columns are shown in Typical Details 1 and 2 of Part 2.

**Base Plate**

Normally a base plate for the encased steel column of a composite column is specified to be the minimum dimension possible to accommodate the anchor bolts anchoring it to the foundation during the erection phase. In doing so, the base plate will interfere the least possible amount with dowels coming up from the foundation to splice with the longitudinal vertical bars of the composite column. The design engineer must provide dowels from the composite column to the foundation to transmit the column load in excess of the allowable bearing stress on the foundation concrete \((\phi \times 0.85 \times f'c)\) times the effective bearing area (the total composite column area less the area of the encased wide flange column base plate). In some cases, depending on the base plate size, it may be necessary to add additional foundation dowels to adequately transmit the load carried by the concrete of the composite column. A typical base plate detail is shown in Typical Detail 4, Part 2. A composite column base plate example is included as Example 5, Part 3.
Erection and Temporary Wind Bracing During Composite Frame Construction

Historically, a structural steel erector is accustomed to working with a steel framed structure that is stabilized as the frame is constructed with moment connections or permanent cross bracing. Composite frames many times are not stable and not fully able to carry lateral loads until after the concrete is poured and cured many floors behind. Because of this fact, it is incumbent on the engineer-of-record to state the assumptions of bare steel frame stability in the contract documents. Either he designs and details the necessary temporary bracing on the drawings or requires the erector to engage a structural engineer to provide it. The engineer-of-record is the most appropriate person to provide this service by virtue of his knowledge of the loads and familiarity with the overall structure. Additional discussions about the design responsibility of steel frames during erection may be found in the AISC Code of Standard Practice. A discussion of composite frames during erection may be found in Reference 15.

Load and Resistance Factor Design (LRFD) of Composite Columns

To qualify as a composite column under the LRFD Specification design procedure, the following limitations must be satisfied as defined in Section 12.1:

1. The cross sectional area of the steel shape, pipe, or tubing must comprise at least four percent of the total composite cross section.
2. Concrete encasement of a steel core shall be reinforced with longitudinal load carrying bars, longitudinal bars to restrain concrete, and lateral ties. Longitudinal load carrying bars shall be continuous at framed levels; longitudinal restraining bars may be interrupted at framed levels. The spacing of ties shall be not greater than two-thirds of the least dimension of the composite cross section. The cross sectional area of the transverse and longitudinal reinforcement shall be at least 0.007 in.² per inch of bar spacing. The encasement shall provide at least 1½-in. of clear cover outside of both transverse and longitudinal reinforcement.
3. Concrete shall have a specified compressive strength of not less than 3 ksi nor more than 8 ksi for normal weight concrete, and not less than 4 ksi for lightweight concrete.
4. The specified minimum yield stress of structural steel and reinforcing bars used in calculating the strength of a composite column shall not exceed 55 ksi.

The required design strength $P_n$ of axially loaded composite columns is defined in the LRFD Specification, Section E2, with modification of certain terms according to Section I2.2. These rules are summarized as follows:

$P_n = \phi_n P_n$, required axial strength

For $\lambda_c \leq 1.5$,

$F_{cr} = (0.658\lambda_c^2) F_{my}$

For $\lambda_c > 1.5$,

$F_{cr} = \frac{0.877}{\lambda_c^2} F_{my}$

$\lambda_c = \frac{KI}{r_m F_{my} / E_m}^{1/2}$

$\phi_c = $ resistance factor for compression = 0.85
$A_s = $ gross area of steel shape
$F_{my} = $ modified yield stress
$E_m = $ modified modulus of elasticity
$F_y = $ specified yield stress of structural steel column, ksi
$E = $ modulus of elasticity of steel, ksi
$K = $ effective length factor
$I = $ unbraced length of column, in.
$r_m = $ radius of gyration of steel shape in plane of buckling, except that it shall not be less than 0.3 times the overall thickness of the composite cross section in the plane of buckling, in.
$A_c = $ net concrete area = $A_s - A_l - A_{in}$, in.²
$A_g = $ gross area of composite section, in.²
$A_l = $ area of longitudinal reinforcing bars, in.²
$E_c = $ modulus of elasticity of concrete = $w_c^{1.5} (f'_c)^{1/2}$, ksi
$w_c = $ unit weight of concrete, lbs./ft³
$f'_c = $ specified compressive strength of concrete, ksi
$F_{cr} = $ specified minimum yield stress of longitudinal reinforcing bars, ksi
$c_1 = $ 0.7
$c_2 = $ 0.6
$c_3 = $ 0.2

The interaction of axial compression and flexure in the plane of symmetry on composite members is defined in Section H1.1, H1.2, and I4 as follows:

For $P_s / \phi_s P_n \geq 0.2$,

$\frac{P_s}{\phi_s P_n} + \frac{8}{9} \left( \frac{M_{ax}}{\phi_s M_{ax}} + \frac{M_{my}}{\phi_s M_{my}} \right) \leq 1.0$ (H1-1a)

For $P_s / \phi_s P_n < 0.2$,

$\frac{P_s}{2 \phi_s P_n} + \left( \frac{M_{ax}}{\phi_s M_{ax}} + \frac{M_{my}}{\phi_s M_{my}} \right) \leq 1.0$ (H1-1b)

$P_n = $ required compressive strength, kips
$P_n = $ nominal compressive strength, kips
$M_{ax} = $ required flexural strength, kip-in.
$M_{n} = $ nominal flexural strength determined from plastic
stress distribution on the composite cross section, kip-in.

\[ \phi_c = \text{resistance factor for compression} = 0.85 \]

\[ \phi_b = \text{resistance factor for flexure} = 0.90 \]

The following information on the determination of the required flexural strength, \( M_n \), is quoted from Section H1.2 of the LRFD Specification, with minor changes in symbols as prescribed in Section I2.

"In structures designed on the basis of elastic analysis, \( M_n \) may be determined from a second order elastic analysis using factored loads. In structures designed on the basis of plastic analysis, \( M_n \) shall be determined from a plastic analysis that satisfies the requirements of Sects. C1 and C2. In structures designed on the basis of elastic first order analysis the following procedure for the determination of \( M_n \) may be used in lieu of a second order analysis:

\[
M_n = B_1 M_{n1} + B_2 M_{n2} \quad \text{(H1-2)}
\]

where

\[ M_{n1} = \text{required flexural strength in member assuming there is no lateral translation of the frame, kip-in.} \]

\[ M_{n2} = \text{required flexural strength in member as a result of lateral translation of the frame only, kip-in.} \]

\[
B_1 = \frac{C_m}{1 - \left( \frac{P_n}{P_t} \right)} \geq 1 \quad \text{(H1-3)}
\]

\[ P_t = A_t F_{my} / \lambda_c^2 \text{ where } \lambda_c \text{ is defined by Formula E2-4 with } K \leq 1.0 \text{ in the plane of bending.} \]

\[ C_m = \text{a coefficient whose value shall be taken as follows:} \]

i. For restrained compression members in frames braced against joint translation and not subject to transverse loading between their supports in the plane of bending,

\[ C_m = 0.6 - 0.4 \left( \frac{M_1}{M_2} \right) \quad \text{(H1-4)} \]

where \( M_1 / M_2 \) is the ratio of the smaller to larger moments at the ends of that portion of the member unbraced in the plane of bending under consideration. \( M_1 / M_2 \) is positive when the member is bent in reverse curvature, negative when bent in single curvature.

ii. For compression members in frames braced against joint translation in the plane of loading and subjected to transverse loading between their supports, the value of \( C_m \) can be determined by rational analysis. In lieu of such analysis, the following values may be used:

for members whose ends are restrained, \( C_m = 0.85 \)

for members whose ends are unrestrained, \( C_m = 1.0 \)

\[
B_2 = \frac{1}{1 - \sum \frac{\Delta_{ds}}{\Delta_{sH}}} \quad \text{(H1-5)}
\]

or

\[
B_2 = \frac{1}{1 - \frac{\sum P_n}{\sum P_t}} \quad \text{(H1-6)}
\]

\[ \sum P_n = \text{required axial load strength of all columns in a story, kips} \]

\[ \Delta_{ds} = \text{translation deflection of the story under consideration, in.} \]

\[ \sum H = \text{sum of all story horizontal forces producing } \Delta_{ds}, \text{ kips} \]

\[ L = \text{story height, in.} \]

\[ P_t = A_t F_{my} / \lambda_c^2 \text{ kips, where } \lambda_c \text{ is the slenderness parameter defined by Formula E2-4, in which the effective length factor } K \text{ in the plane of bending shall be determined in accordance with Sect. C2.2, but shall not be less than unity.} \]

The nominal flexural strength \( M_n \) is determined for the plastic stress distribution on the composite cross section as shown in Fig. 4. The plastic neutral axis is first determined such that there is equilibrium of axial forces in the concrete, reinforcing steel and embedded steel column. The nominal flexural strength \( M_n \) is determined as the summation of the first moment of axial forces about the neutral axis. See Example 2, Part 3.

In the determination of the concrete compressive axial force, a concrete compressive stress of \( 0.85 f'_c \) is assumed uniformly distributed over an equivalent stress block bounded by the edges of the cross section and a straight line parallel to the plastic neutral axis at a distance \( a = \beta_1 c \), where \( c \) is the distance from the edge of the cross section to the plastic neutral axis, and,

\[ \beta_1 = 0.85 \text{ for } f'_c \leq 4 \text{ ksi} \]

\[ \beta_1 = 0.85 - 0.05(f'_c - 4) \geq 0.65 \text{ for } f'_c > 4 \text{ ksi} \]

These assumptions are contained in the ACI 318-89 Code (Section 10.2.7.3).

**Comparison Between LRFD and Strain Compatibility Methods**

Guidelines for the design of composite columns were first introduced into the ACI Building Code in 1971 (ACI 318-71). With the widespread use and popularity of composite columns in the 1970s and 1980s, many engineers designed composite columns according to these principles, which are essentially the same ones used for conventional reinforced concrete columns.

The current rules for designing composite columns by the
ACI approach are found in ACI 318-89, Chapter 10. The method essentially is one based on the assumption of a linear strain diagram across the composite cross section with the maximum failure strain at ultimate load defined as 0.003. With these assumptions, it is possible to generate strength capacities of the cross section for successive assumed locations of the neutral axis. Strains at each location of the cross section are converted to stress for the usual assumption of a linear stress-strain curve for reinforcing steel and structural steel. The first moment of forces in each element of concrete, structural steel, and reinforcing steel is taken about the neutral axis to generate a point (axial load and moment) on an interaction curve.

A comparison between the strain compatibility approach and the LRFD approach is shown in Figs. 5 through 7. Interaction curves (axial load vs. moment) are plotted covering the wide range of composite column sizes (28×28 in., 36×36 in., 48×48 in.) steel column sizes (minimum of four percent of the composite column cross section to maximum W 14×730) and reinforcing steel percentages (one percent to four percent) that are likely to be found in practice. Examination of these figures reveals the following comparison:

1. The ACI approach yields curves that are parabolic in nature while the AISC curves are essentially bilinear.
2. The two methods yield pure moment capacities that are very close to each other. The maximum difference is approximately 15 percent with most values much closer than that. LRFD in all cases predicts higher moment values.
3. The two methods yield pure axial load capacities that are reasonably close when the steel column constitutes a small part of the total column capacity, but are significantly different as the steel column becomes larger. With larger steel column sizes, the LRFD approach yields axial capacities as much as 30 percent larger than ACI. This comparison, however, is not very meaningful because the ACI approach essentially does not recognize pure axially loaded columns with its minimum eccentricity provisions.
4. Large differences in capacity are predicted (as much as 50 percent) for composite columns having small steel columns. The ACI method yields significantly larger axial loads for a given moment than the LRFD method. This difference is most striking in the intermediate range of the curve.
5. With larger steel columns, the LRFD curve is mostly above (predicts higher values) the ACI curve. As the steel column section becomes lighter, the ACI curve tends to be above the LRFD curve, particularly in the middle ranges of eccentricity.
6. It can generally be stated that, as the steel column becomes a larger portion of the total column capacity, design economy can be realized by designing using the LRFD approach. When the steel column becomes
smaller (the column is more like a conventional concrete column), the ACI method is more economical in design. Reference 23 also presents a comparison of design methods.

Description of the Composite Beam-Column Load Tables

Design tables are presented in Part 4 of this Guide to assist the engineer in the rapid selection of the most economical composite column to resist factored values of axial load and moment. The tables are based on the LRFD Specification requirements outlined in the previous sections. The tables have been set up to follow the general format of the LRFD Manual, including the column tables in Part 2 (Axial Loaded Steel Columns) and Part 4 (Axially Loaded Composite Columns) of the Manual, because these are already familiar to most design engineers. The tables indicate the following parameters from which the engineer can select a design (Refer to sample table at beginning of Part 4 of this Guide):

Item 1: Composite Column Size ($b \times h$, in.). The composite column size ($b \times h$) is indicated in inches in the upper right corner of the table. Note that the $x-x$ axis is always the strong axis of the steel column and is in the direction of $b$. The $y-y$ axis is always the weak axis of the steel column and is in the direction of $h$. The table covers square and rectangular sizes varying from 16 inches to 36 inches in four-inch increments.

Item 2: Concrete Strength ($f'_c$, ksi). Concrete compression strength is indicated in the top right corner for 3 and 8 ksi. All concrete is assumed to be normal weight concrete weighing 145 pcf. Linear interpolation can be used for concrete strengths between 3 and 8 ksi.

Item 3: Reinforcing Bar Yield Strength ($F_{yr}$, ksi). All longitudinal and transverse reinforcing steel in the table is based on ASTM A615 Grade 60 reinforcing steel.

Item 4: Steel Column Size. Steel column size is listed across the top of the table. Sizes tabulated include all W8, W10, W12, and W14 wide flange shapes that are listed in the steel column tables in Part 4 of the LRFD manual. They include W8 (35 to 67), W10 (39 to 112), W12 (50 to 336), and W14 (43 to 426).

Item 5: Steel Grade ($F_y$, ksi). Steel grade is presented across the top of the page for both A36 and Grade 50 steel.

Item 6: Reinforcement. Information on column reinforcement is indicated in the extreme left column and includes the percentage of vertical steel, area of steel ($A_r$, in.$^2$), number, size of bar, pattern of vertical steel, and lateral tie size and spacing (see Fig. 2 for notation). The table covers steel percentages as close as practical to 0.5 percent, 1 percent, 2 percent, 3 percent, and 4 percent steel. If zeroes are tabulated, it indicates steel cover or spacing requirements could not be satisfied for the steel percentage indicated. Bar arrangements and their designations are shown in Fig. 2.

Item 7: Unbraced Length ($KL$, ft). Axial load capacities are tabulated for unbraced lengths of 0, 11, 13, 17, 21, 25, and 40 feet.

Item 8: Axial Design Strength (Nominal Axial Strength times Resistance Factor, $\phi P_{n}$, kips). For each unbraced length, $KL$, equations E2-1, E2-2, E2-3, and E2-4 are used to calculate the nominal axial strength which is multiplied by $\phi = 0.85$ and tabulated in the column marked 8.

Item 9, 10, and 11: Available Required Flexural Strength (Uniaxial Moment Capacity, $M_{ur}, M_{ur}$, ft-kips). For each ratio of applied factored axial load to $\phi$, times the nominal axial capacity, $P_{n}/\phi P_{n}$, available uniaxial moment capacity is tabulated by solving equation H1-1a or H1-1b as applicable. Note that these moment capacities are uniaxial capacities and are applied independently. Biaxial moment capacities are not tabulated.

Item 12: Euler Buckling Term ($C_{e}, C_{e}$, kip-ft$^2$). The second order moment, $M_c$, can be taken directly from a second order elastic analysis, or it can be calculated from a first order elastic analysis by using LRFD equations H1-1 through H1-6. To aid the designer in such a calculation, the terms $C_{e}$ and $C_{e}$ are tabulated for each column configuration. The following definitions apply.

Fig. 7. Interaction curve comparisons ACI vs. LRFD.
Thus, the Euler buckling load needed for the calculation is simply

\[ P_e = \frac{10,000C_e}{(KL)^2} \]

**Item 13:** Radius of Gyration \((r_{mx}, r_{my}) \text{ in.}\). To compare the axial design strength for buckling about each axis, and to assist the designer in determining column capacity for unbraced lengths not shown in the table, values of \(r_{mx}\) and \(r_{my}\) are tabulated for each column configuration.

Note that the development of the moment capacities listed in the tables is based on a numerical calculation of the contribution of the encased shape, the precise number and location of reinforcing bars as prescribed in the bar arrangements of Fig. 2, and the concrete. This is in lieu of the approximate plastic moment capacity expression prescribed by the LRFD Commentary equation C-I4-1. The approximate expression was used in the moment capacities tabulated in the composite column tables presently in the LRFD Manual and will result in some differences when compared to the more precise method used in the new composite beam-column tables in this Guide.

The following factors should be considered in the use of the tables:

1. Where zeroes exist in the tables, no bar pattern from the configurations considered in Fig. 2 exists that would satisfy bar cover and spacing requirements between bars, or between bars and the surface of the encased steel column (Refer to Fig. 3).
2. Moment capacity tabulated is the uniaxial moment capacity considering each axis separately.
3. Only column configurations conforming to all the limitations in the LRFD Specification (Section 12.1) are tabulated.
4. Capacities shown are only applicable to the bar arrangements shown in Fig. 2.
5. The designer must determine in each case that necessary clearances are available for beams framing into the steel column without interrupting the vertical bars.
6. Linear interpolation can be used to determine table values for concrete strengths between 3 and 8 ksi.

Specific instruction for using the tables are given at the beginning of the tables, Part 4 of this Guide. The background for the development of the tables is presented in Examples 1 and 2, Part 3 of this Guide.

Typical Detail 2: Composite column cross section.
Typical Detail 3: Composite column joint.
Typical Detail 4: Composite column baseplate.
Typical Detail 5: Tree column in a composite frame.
PART 3: DESIGN EXAMPLES

Example 1:
Compute the axial load capacity of a 48×48-in. composite column with an encased W 14×730. Compute capacity for unbraced length equal to 11'-0 and 40'-0. Use $f_y' = 5$ ksi, $F_y = 60$ ksi, 20 - #14 (6x - 6y) and $w_c = 145$ pcf. See Fig. B-1.

W14×730 properties are:
- $A_s = 215$ in.²
- $d = 22.42$ in.
- $t_w = 3.07$ in.
- $b_f = 17.89$ in.
- $t_f = 4.91$ in.
- $r_i = 8.17$ in.
- $r_o = 4.69$ in.

Solution:
1. Compute section properties.

   Total area of longitudinal reinforcing bars = $20 \times 2.25 = 45.0$ in.²
   Gross section area of concrete column = $48 \times 48 = 2,304$ in.²
   Percentage of longitudinal reinforcing bars = $45.0 / 2,340 = 1.95$ percent
   Percentage of steel shape = $215 / 2,304 = 9.33$ percent $> 4$ percent  o.k.
   Net area of concrete = $2,304 - 45 - 215 = 2,044$ in.²

   $F_{my} = F_y + (c_1 \times F_y \times A_y / A_s) + (c_2 \times f_y' \times A_c / A_s)$
   (Use $F_y = 60$ ksi instead of 55 ksi limitations—see discussion under "Shear Connections")
   
   $= 50 + (0.7 \times 60 \times 45 / 215) + (0.6 \times 5 \times 2,044 / 215)$
   
   $= 87.31$ ksi

   $E_c = w_c^{1.5} \times f_y'^{0.5} = 145^{1.5} \times 5^{0.5} = 3,904$ ksi

   $E_{in} = E_c + (c_3 \times E_c \times A_s / A_s)$
   
   $= 29,000 + (0.2 \times 3,904 \times 2,044 / 215) = 36,423$ ksi

<td>Column Size (b x h): 60 x 48</td>
<td></td>
</tr>
</tbody>
</table>

**Notes:**
1. \( P_{ef} = P_{ef}(KL)^2 / 10,000 \text{ (kip-ft)} \)
2. \( C_{ef} = \frac{P_{ef}(KL)^2}{10,000} \text{ (kip-ft)} \)
3. See Figure 5 for definition of bar arrangement (esp. - my). NW = normal weight concrete.

4. \( M_{ef} = 0.85M_{ef} \) and \( M_{ef} = 0.90M_{ef} \) when \( P_{ef} / (\phi_0 P_0) = 0.0 \)
\[ r_{m1} = r_{m2} = 0.3 \times 48 = 14.4 \text{ in.} > r_s = 8.17 \text{ in.} \]
\[ C_{cr} = C_{e} = P_{cr} = KL^2 / 10,000 = A_s \times E_s (\pi r_m)^2 / 1,440,000 \]
\[ = 215 \times 36,423 \times (3.1416 \times 14.4)^2 / 1,440,000 \]
\[ = 11,130 \text{ kip-ft}^2 \]

2. Axial load capacity

For \( KL = 0' - 0 \)

\[ F_{cr} = F_{my} = 87.31 \text{ ksi} \]
\[ \phi P_n = \phi A_s F_{cr} = 0.85 \times 215 \times 87.31 = 15,960 \text{ kips} \]

For \( KL = 11' - 0 \)

\[ \lambda_c = KL(F_{my} / E_m)^{0.5} / r_m / \pi \]
\[ = KL(87.31 / 36.423)^{0.5} / 14.4 / 3.1416 = 0.001082KL \]
\[ = 11 \times 12 \times 0.001082 = 0.143 < 1.5 \]
\[ F_{cr} = 0.658^{0.5} \times F_{my} = 0.658^{0.143 \times 0.143} \times 87.31 = 86.57 \text{ ksi} \]
\[ \phi P_n = \phi A_s F_{cr} = 0.85 \times 215 \times 86.57 = 15,820 \text{ kips} \]

For \( KL = 40' - 0 \)

\[ \lambda_c = 0.001082KL = 40 \times 12 \times 0.001082 = 0.520 < 1.5 \]
\[ F_{cr} = 0.658^{0.520 \times 0.520} \times 87.31 = 78.0 \text{ ksi} \]
\[ \phi P_n = \phi A_s F_{cr} = 0.85 \times 215 \times 78.0 = 14,250 \text{ kips} \]

The calculated values of \( \phi P_n \) agree with the values circled in Table A, Example 2, which have been rounded.
Example 2:
Compute the interaction curves of the composite column described in Example 1. See Fig. B-1.

Solution:
1. Coordinates of reinforcing bars.

</table>

2. Nominal flexural strength about x-axis.

\[ f_{\text{c85}} = 0.85f' = 0.85 \times 5 = 4.25 \]

\[ F_{\text{y85}} = F_y - f_{\text{c85}} = 50 - 4.25 = 45.75 \]

\[ F_{\text{yr85}} = F_{\text{yr}} - f_{\text{c85}} = 60 - 4.25 = 55.75 \]

\[ \beta = 0.85 - 0.05(f' - 4) = 0.80 \]

In general, successive approximations are required to determine the location of the plastic neutral axis. Here, trial values of the distance from the plastic neutral axis to the bottom of the section, \( Y_b \), and to the top of the section, \( Y_a \), are assumed as follows:

\[ Y_b = 30.69 \text{ in.} \]

\[ Y_a = 48 - Y_b = 48 - 30.69 = 17.31 \text{ in.} \]

\[ a = \beta Y_a = 0.8 \times 17.31 = 13.85 \text{ in.} \]

\[ Y_a = 48 - a = 48 - 13.85 = 34.15 \text{ in.} \]
Since the summation of forces is approximately zero, the assumed location of the plastic neutral axis is correct.

\[ \phi M_{ax} = 0.9 \times 14,009 = 12,608 \text{ kip-ft} \]

Calculate the uniaxial moment capacity from Eqs. H1-1a and H1-1b for assumed values of the load ratio \( R_u = P_u / \phi P_c \).

\[ M_{ax} = 12,608 \times (1 - R_u) \times 9 / 8 \quad \text{if } R_u \geq 0.2 \]
\[ M_{ax} = 12,608 \times (1 - R_u / 2.0) \quad \text{if } R_u < 0.2 \]

Points on the interaction curve are calculated as follows:

\[ R_u \quad 0.0 \quad 0.2 \quad 0.3 \quad 0.4 \quad 0.5 \quad 0.7 \quad 0.9 \]
\[ M_{ax} \quad 12,610 \quad 11,350 \quad 9,930 \quad 8,510 \quad 7,090 \quad 4,260 \quad 1,420 \]

These values agree with the circled values in Table A.

3. Nominal flexural strength about y-axis.

Try

\[ X_s = 25.55 \text{ in.} \]
\[ X_f = 48 - X_s = 48 - 25.55 = 22.45 \text{ in.} \]
\[ a = \beta X_a = 0.8 \times 22.45 = 17.96 \text{ in.} \]
\[ X_a = 48 - a = 48 - 17.96 = 30.04 \text{ in.} \]

\end{align*}
\]

These values agree with the circled values in Table A.
Example 3:
Design a 20\times20\text{-in.} composite column with an encased W\text{-shape to resist a factored axial load of 470 kips and a factored moment about the x\text{-axis of 350 kip\text{-ft.}} The loads are obtained from a second order analysis. Use \( f_e \leq 5 \text{ ksi}, \quad F_y = 60 \text{ ksi}, \quad F_s = 50 \text{ ksi, and } KL = 17 \text{ ft.} \)

Solution:
1. Calculate relative eccentricity:
   \[ M_u / (P_e t) = 350 / (470 \times 1.67) = 0.45 \]
2. Determine trial load ratio:
   \[ M_u / (P_e t) > 0.33, \quad \text{use } R_u = 0.3 \]
3. Calculate required axial strength:
   \[ \phi_e P_e = P_u = 470 / 0.3 = 1,567 \text{ kips} \]
4. Select trial column:
   Try 20\times20\text{-in. composite column, W8\times58 column, 4-\#7 (2x - 2y)}
   \[ \phi_e P_e = 1,570 \text{ kips for } KL = 17 \text{ ft} \]
5. Calculate load ratio for trial column:
   \[ R_u = P_u / \phi_e P_e = 470 / 1,570 = 0.33 \]
6. Determine uniaxial moment capacity:
   From Table B with \( R_u = P_u / \phi_e P_e = 0.3, M_{ax} = 354 \text{ kip\text{-ft}} \)
7. Compare to factored moment:
   \[ M_{ax} = 354 \text{ kip\text{-ft}} \text{ (from Table B)} > 350 \text{ kip\text{-ft required}} \quad \text{o.k.} \]
   Use 20\times20\text{-in. composite column with W8\times58 (F_y = 50 ksi), } f_e' = 5 \text{ ksi, 4-\#7 bars (2x - 2y)} \text{ vertical bars and #3 ties at 13 in.}

#### Notes:

1. \( C_{ax} = P_{nf}(K_{ax} \cdot L^{2}) / 10,000 \) (kip-ft), \( C_{by} = P_{nf}(K_{by} \cdot L^{2}) / 10,000 \) (kip-ft), in ft. \( r_{ax} \) and \( r_{by} \) in inches.

2. Zeros in columns for \( P_{nf}, M_{ax}, \) and \( M_{by} \) indicate that no suitable reinforcing bar arrangement is available for the indicated steel percentage.

3. See Figure 2 for definition of bar arrangement (nx - by). NW = normal weight concrete.

4. \( M_{by} = \phi M_{by} \) and \( M_{ax} = \phi M_{ax} \) when \( P_{sf} / (q_{y} P_{nf}) = 0.0 \).
Example 4:
Design a 20×20-in. composite column with an encased W-shape to resist a factored axial load of 1,190 kips and a factored moment about the x-axis of 180 kip-ft. The loads are obtained from a second order analysis. Use $f' = 5$ ksi, $F_y = 60$ ksi, $F_y = 50$ ksi, and $KL = 17$ ft.

Solution:
1. Calculate relative eccentricity:
   \[ \frac{M_e}{P_e} = \frac{180}{(1,190 \times 1.67)} = 0.09 \]
2. Determine trial load ratio:
   \[ \frac{M_e}{P_e} < 0.10, \text{ use } R_e = 0.7 \]
3. Calculate required axial strength:
   \[ \phi \cdot P_e = P_e / R_e = 1,190 / 0.7 = 1,700 \text{ kips} \]
4. Select trial column:
   Try 20×20-in. composite column, W8×67 column, 4-#9 (2x - 2y)
   \[ \phi \cdot P_e = 1,700 \text{ kips for } KL = 17 \text{ ft} \]
5. Calculate load ratio for trial column:
   \[ R_e = P_e / \phi \cdot P_e = 1,190 / 1,700 = 0.7 \]
6. Determine uniaxial moment capacity:
   From Table B with $R_e = P_e / \phi \cdot P_e = 0.7, M_{ax} = 183 \text{ kip-ft}$
7. Compare to factored moment:
   \[ M_{ax} = 183 \text{ kip-ft (from Table B)} > 180 \text{ kip-ft required } \text{ o.k.} \]
Use 20×20-in. composite column with W8×67 ($F_y = 50$ ksi), $f' = 5$ ksi, 4-#9 bars (2x - 2y) vertical bars and #3 ties at 13 in.
Example 5:

Design the base plate of a 18×18-in. composite column with an encased W10×54 of $F_y = 36$ ksi, $f' = 8$ ksi, and 4-#8 grade 60 longitudinal bars. Factored axial load $P_f = 1,000$ kips, $KL = 31$ ft. Use $f' = 3$ ksi for footing. Assume $(A_2 / A_1)^{1/2} \geq 2$. See Fig. B-2 for nomenclature. Refer to AISC LRFD Manual, p. 2-101 for base plate design procedure.

Solution:

Base plate will be designed for the portion of the factored axial load resisted by the W10×54.

W10×54 properties:

- $b_y = 10.03$ in.
- $d = 10.09$ in.
- $t_y = 0.615$ in.
- $A_y = 15.8$ in.$^2$

Try base plate 12×12 in.

1. Compute axial load carried by W10×54 based on the contribution of W10×54 to the total column capacity.

\[ F_{my} = \bar{F}_y + F_p (\frac{A_y}{A_2}) + c f' (\frac{A_y}{A_1}) \]

\[ = 36 + (0.7 \times 60 \times 3.16 / 15.8) + (0.6 \times 8(18 \times 18 - 15.8 - 4 \times 0.79) / 15.8) \]

\[ = 137.07 \text{ ksi} \]

Portion of factored axial load resisted by W10×54 is:

\[ P_f = 1,000 \times 36 / 137.07 = 262.64 \text{ kips} \]

2. Compute $m$ and $n$.

\[ m = (N - 0.95d) / 2 = (12 - 0.95 \times 10.09) / 2 = 1.207 \]

\[ n = (B - 0.8bt) / 2 = (12 - 0.8 \times 10.03) / 2 = 1.988 \text{ governs} \]

Fig. B-2. Column base plates.

---

$P_6$ = factored load contributory to area enclosed by steel shape, kips

$P_2$ = Factored axial load resisted by steel shape, kips

$A_1$ = Area of base plate, in.$^2$

$A_2$ = Full cross sectional area of concrete support, in.$^2$

$A_{NH}$ = Area of H-shaped portion of base plate in light columns, in.$^2$

$F_y$ = Specified minimum yield stress of steel, ksi

$f'$ = Specified compressive strength of concrete, ksi

$t_p$ = Thickness of base plate, in.

$\Phi_c$ = Resistance factor for concrete = 0.6

$\Phi_p$ = Resistance factor for base plate = 0.9

© 2003 by American Institute of Steel Construction, Inc. All rights reserved. This publication or any part thereof must not be reproduced in any form without permission of the publisher.
3. Concrete bearing stress.
   \[ \phi 0.85f'_c \left( \frac{A_2}{A} \right)^{0.5} = 0.6 \times 0.85 \times 3 \times 2 = 3.06 \text{ ksi} \]

4. Check concrete bearing under base plate.
   \[ P' / (BN) = 262.64 / (12 \times 12) = 1.824 \text{ ksi} < 3.06 \quad \text{o.k.} \]

5. Compute factored load contributary to the area enclosed by W10×54.
   \[ P_e = P_h/d / (BN) = 262.64 \times 10.03 \times 10.09 / (12 \times 12) = 184.58 \text{ kips} \]

   \[ A_H = P_e / (0.6 \times 1.7 \times f_c') = 184.58 / (0.6 \times 1.7 \times 3) = 60.32 \text{ in.}^2 \]

7. Compute \( c \).
   \[ c = (d + b_f - t_f - ((d + b_f - t_f)^2 - 4(A_H - t_f b_f)^{0.5}) / 4 \]
   \[ = (10.09 + 10.03 - 0.615 - ((10.09 + 10.03 - 0.615)^2 - 4 \times (60.32 - 0.615 \times 10.03))^{0.5}) / 4 \]
   \[ = 1.676 \]

8. Compute base plate thickness.
   \[ t_p = \max(m, n) \times \left( 2P_e / (0.9F_c BN) \right)^{0.5} \]
   \[ = 1.988 \times \left( 2 \times 262.64 / (0.9 \times 36 \times 12 \times 12) \right)^{0.5} = 0.667 \text{ in.} \]
   \[ t_p = c(2P_e / 0.9F_c A_p)^{0.5} \]
   \[ = 1.676 \times \left( 2 \times 184.58 / (0.9 \times 36 \times 60.32) \right)^{0.5} = 0.728 \text{ in.} \]

   Use \( \frac{3}{4} \)-in. plate.

9. Design dowels to foundation.

   Allowable compression transfer by concrete:
   \[ = 2\phi 0.85f'_c (\text{column area} - \text{base plate area}) \]
   \[ = 2 \times 0.6 \times 0.85 \times 3 (18 \times 18 - 12 \times 12) \]
   \[ = 550.8 \text{ kips} \]

   Required compression transfer by concrete:
   \[ = 1,000 - 262.64 \]
   \[ = 737.36 \text{ kips} > 550.8 \text{ kips} \quad \text{Dowels are required.} \]

   Required area of dowels:
   \[ A_v (\text{req'd}) = (737.36 - 550.8) / 60 = 3.11 \text{ in.}^2 \]
   \[ A_v (\text{min.}) = 0.005A_g = 0.005 \times 18 \times 18 = 1.62 \text{ in.}^2 \quad (ACI 318-89 Section 15.8.2.1) \]

   Use 4-#8, \( A_v (\text{provided}) = 4 \times 0.79 = 3.16 \text{ in.}^2 > 3.11 \quad \text{o.k.} \)

   Embed dowels 22 bar diameters (for 3,000 psi concrete) into foundation (ACI 318-89 Section 12.3.1) = 22 \times 1.00 = 22 \text{ in.}

   Dowel projection into column = 30 bar diameters (ACI 318-89 Section 12.16.1) = 30 \times 1.00 = 30 \text{ in.}
PART 4: LRFD COMPOSITE BEAM-COLUMN DESIGN TABLES

Instructions for Using LRFD Composite Beam-Column Design Tables

1. Determine the relative magnitude of the column eccentricity by dividing the applied factored moment, $M_u$ (ft-kips), by the product of the applied factored axial load, $P_u$ (kips), and the composite column dimension in the plane of bending, $t$.

2. Select a first trial value of the load ratio, $R_u$, depending on the relative magnitude of eccentricity calculated from step one, as follows:

   $R_u = 0.3$, if $M_u / (P_u t) \geq 0.33$ (large eccentricity)
   $R_u = 0.5$, if $0.10 M_u / (P_u t) < 0.33$ (moderate eccentricity)
   $R_u = 0.7$, if $M_u / (P_u t) \leq 0.10$ (large eccentricity)

3. Compute required axial design strength $\phi P_u = P_u / R_u$.

4. For a given desired column size $(b \times h)$ and concrete strength $(f'_c)$, and a known effective unbraced length $(KL)$, select a trial column having $\phi P_u$ approximately equal to $P_u$.

5. Compute the load ratio, $R_u = P_u / (\phi P_u)$ for the trial column selected.

6. From the Table, for $R_u = P_u / (\phi P_u)$ as calculated from Step 5, find the uniaxial moment capacity $M_{ux}$ (or $M_{uy}$ as applicable).

7. Compare to the factored moment.

   If $M_{ux} (or M_{uy}) \geq M_u$ (and reasonably close to), trial column is satisfactory.
   If $M_{ux} (or M_{uy}) < M_u$, trial column is not satisfactory.

8. If column is not satisfactory, repeat steps four through seven with a new trial column. Adjustments to get the required capacity can be made by changing any of the following variables:

   a. column size
   b. concrete strength
   c. WF column size
   d. percentage of vertical steel

   If $M_{ux} (or M_{uy}) \geq M_u$, reenter the Tables with a larger $R_u = P_u / (\phi P_u)$ ratio.
   If $M_{ux} (or M_{uy}) < M_u$, reenter the Tables with a smaller $R_u = P_u / (\phi P_u)$ ratio.
The tabular information in the printed version of this design guide (pages 30 through 309) has been omitted in the posted version to minimize the file size.

The tables are available in hard copy to members and ePubs subscribers free of charge by contacting solutions@aisc.org, or 866.ASK.AISC.
PART 5: COMPOSITE COLUMN
PROGRAM CMPOL

A computer program named CMPOL has been developed to generate composite column design tables as described in Part 4. The program may be used to generate the tables in either LRFD or ASD format. It is available through AISC. For further information and/or to place your software order, call (312)670-2400.

The program is contained on a high quality 5¼-in. diskette or 3½-in. disk in executable form and may be copied to a hard disk. It will run on any IBM compatible computer (PC/XT/AT 286 or 386 or Model PS/2) with at least 512K installed RAM. A math coprocessor is optional.

The input data for CMPOL is all interactive. The procedure for running the program is as follows:

1. Access drive A or go to the subdirectory containing the program if it is located on the hard disk.
2. Set the printer in a condensed mode. This can be done by typing CONDENSE to invoke a batch file named RCOMP.BAT. The batch file automatically uncondenses the printer after the printing is finished.
3. Type CMPOL. A heading will appear on the screen followed by a question as to where the output is to be directed. Enter 2 for printer.
4. Questions will appear on the screen prompting the user to enter the following data:
   - Design Method. Enter 1 for LRFD, 2 for the approximate procedure as used in the LRFD Manual and described in the text to this guide, 3 for ASD.
   - Unbraced Length (ft). Input 7 values of unbraced length desired.
   - Vertical Reinforcing Bar Splice Type. (1 = bearing or mechanical butt splice, 2 = normal lap splice, 3 = tangential lap splice.) This selection impacts the bar positioning for clearance and cover checks.
   - Column Width (in.). Input minimum, maximum, and increment of column width. If the minimum and maximum are equal, then enter the increment as 1 to avoid an error.
   - Column Depth (in.). Input minimum, maximum, and increment of column depth as described above for column width.
   - Concrete strength (ksi). Input minimum, maximum, and increment of 28 day concrete strength entering the increment of 1 if the minimum and maximum are equal.
   - Concrete Unit Weight (pcf). This value is used in the determination of the modulus of elasticity for concrete.
   - Clear cover to reinforcing steel (in.). Input clear cover to reinforcing steel each direction and clear cover to rolled shape. All three values will normally be 1.5 in.
   - Reinforcing Steel Yield Strength (ksi).
   - Reinforcing Steel Size (integer number). Input minimum and maximum size of vertical reinforcing bars desired.
   - Reinforcing Steel Ratio (decimal number, i.e., 0.01). Input five percentages of reinforcing steel to be analyzed (typically 0.005, 0.01, 0.02, 0.03, 0.04).
   - Beam Clearance, Each Direction (in.). This number defines the clearance at the centerline of the column in each direction which is to be kept clear of vertical bars so that a beam may frame to the embedded rolled shape.
   - Embedded WF Shape. Nominal Depth (in.) Weight (PLF). Input the minimum and maximum W shape size to be included in the tables.
5. Tabular output will be sent to the printer and will be as shown in Appendices C and D. Note that some printers may not print the character "phi" (ϕ) in which case it will appear as an "m." A sample input screen and output are shown on the following pages.
Design method (1 = LRFD exact, 2 = LRFD approximate, 3 = ASD)? 1
Input 7 unbraced length (ft) to be analyzed? 0 11 13 17 21 25 40
Type of splice (1 = bearing, 2 = normal lap, 3 = tangential lap)? 3
Input min., max. & increment of column width (in)? 32 32 1
Input min., max. & increment of column depth (in)? 32 32 1
Input min., max. & increment of concrete fc (ksi)? 3 3 1
Input unit weight of concrete (pcf)? 145
Input clear cover CRx, CRy, CRw (in)? 1.5 1.5 1.5
Input fy (ksi) of reinforcing steel? 60
Input min., max. size of reinforcing steel? 7 18
Input 5 percentages of reinf. steel to be analyzed? .005 .01 .02 .03 .04
Input beam clearance reqd. in N-S & E-W dir. (in)? 5.5 5.5
Input min., max W shape (ND1, ND2, NW2)? 12 152 12 170

Do you want to run CMPOL again (1 = yes, 0 = no)? 0

Stop—program terminated.

C: I READY I CMPOL
